Contents

Example data $\dots \dots \dots \dots \dots \dots \dots$									1
Tabulate $V(D)J$ allele, gene or family usage by sample		 							1
Tabulating gene abundance using additional groupings									4

The 'alakazam' package provides basic gene usage quantification by either sequence count or clonal grouping; with or without consideration of duplicate reads/mRNA. Additionally, a set of accessory functions for sorting and parsing V(D)J gene names are also provided.

Example data

A small example Change-O database, ExampleDb, is included in the alakazam package. Gene usages analysis requires only the following columns:

- V_CALL
- D_CALL
- J_CALL

However, the optional clonal clustering (CLONE) and duplicate count (DUPCOUNT) columns may be used to quantify usage by different abundance criteria.

```
# Load required packages
library(alakazam)
library(dplyr)
library(scales)
# Subset example data
data(ExampleDb)
```

Tabulate V(D)J allele, gene or family usage by sample

The relative abundance of V(D)J alleles, genes or families within groups can be obtained with the function <code>countGenes</code>. To analyze differences in the V gene usage across different samples we will set <code>gene="V_CALL"</code> (the column containing gene data) and <code>groups="SAMPLE"</code> (the columns containing grouping variables). To quantify abundance at the gene level we set <code>mode="gene"</code>:

```
## # A tibble: 4 x 4
               SAMPLE [2]
## # Groups:
##
     SAMPLE
                GENE SEQ_COUNT SEQ_FREQ
##
      <chr>
                          <int>
                                    <dbl>
               <chr>>
        +7d IGHV3-49
                             699
## 1
                                    0.699
## 2
        -1h IGHV3-9
                             83
                                    0.083
## 3
        -1h IGHV5-51
                             60
                                    0.060
## 4
        -1h IGHV3-30
                             58
                                    0.058
```

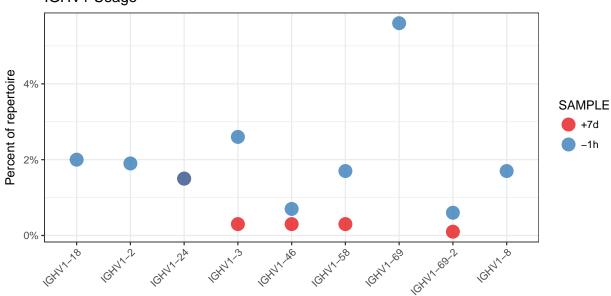

In the resultant data.frame the SEQ_COUNT columns is the number of raw sequences within each SAMPLE group for the given GENE. SEQ_FREQ is the frequency of each GENE within the given SAMPLE.

Below we plot only the IGHV1 abundance by filtering on the GENE column to only rows containing IGHV1 family genes. We extract the family portion of the gene name using the getFamily function. Also, we take advantage of the sortGenes function to convert the GENE column to a factor with gene name lexicographically ordered in the factor levels (method="name") for axis ordering using the ggplot2 package. Alternatively, we could have ordered the genes by genomic position by passing method="position" to sortGenes.

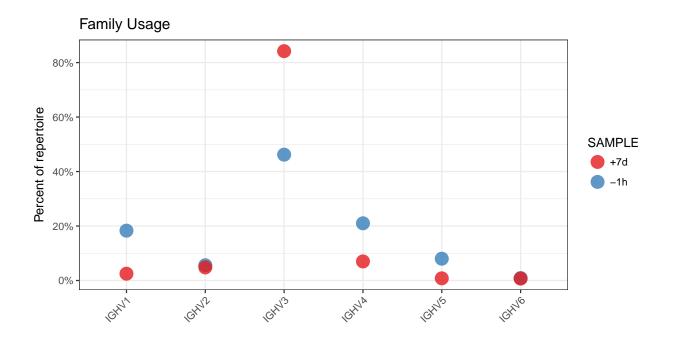

```
# Assign sorted levels and subset to IGHV1
ighv1 <- gene %>%
    mutate(GENE=factor(GENE, levels=sortGenes(unique(GENE), method="name"))) %>%
    filter(getFamily(GENE) == "IGHV1")

# Plot V gene usage in the IGHV1 family by sample
g1 <- ggplot(ighv1, aes(x=GENE, y=SEQ_FREQ)) +
    theme_bw() +
    ggtitle("IGHV1 Usage") +
    theme(axis.text.x=element_text(angle=45, hjust=1, vjust=1)) +
    ylab("Percent of repertoire") +
    xlab("") +
    scale_y_continuous(labels=percent) +
    scale_color_brewer(palette="Set1") +
    geom_point(aes(color=SAMPLE), size=5, alpha=0.8)
plot(g1)</pre>
```

Alternatively, usage can be quantified at the allele (mode="allele") or family level (mode="family"):

Tabulating gene abundance using additional groupings

The groups argument to countGenes can accept multiple grouping columns and will calculated abundance within each unique combination. In the examples below groupings will be perform by unique sample and isotype pairs (groups=c("SAMPLE", "ISOTYPE")). Furthermore, instead of quantifying abundance by sequence count we will quantify it by clone count. Meaning, each clone will be counted only once regardless of how many sequences the clone represents.

Clonal citeria are adding by passing a value to the clone argument of countGenes (clone="CLONE").

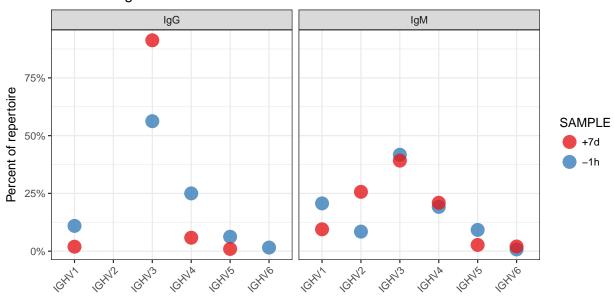

```
# Quantify V family clonal usage by sample and isotype
family <- countGenes(ExampleDb, gene="V_CALL", groups=c("SAMPLE", "ISOTYPE"),</pre>
                      clone="CLONE", mode="family")
head(family, n=4)
## # A tibble: 4 x 5
## # Groups:
               SAMPLE, ISOTYPE [2]
     SAMPLE ISOTYPE GENE CLONE_COUNT CLONE_FREQ
##
##
      <chr>
              <chr> <chr>
                                 <int>
                                             <dbl>
## 1
        -1h
                IgM IGHV3
                                    222
                                         0.4172932
## 2
        -1h
                IgM IGHV1
                                    110
                                         0.2067669
                IgM IGHV4
        -1h
                                    102
                                         0.1917293
## 3
## 4
        +7d
                IgG IGHV3
                                     94
                                         0.9126214
```

The output data.frame contains the additional grouping column (ISOTYPE) along with the CLONE_COUNT and CLONE_FREQ columns that represent the count of clones for each V family and the frequencies within the given SAMPLE and ISOTYPE pair, respectively.

```
# Subset to IgM and IgG for plotting
family <- filter(family, ISOTYPE %in% c("IgM", "IgG"))</pre>
```

```
# Plot V family clonal usage by sample and isotype
g3 <- ggplot(family, aes(x=GENE, y=CLONE_FREQ)) +
    theme_bw() +
    ggtitle("Clonal Usage") +
    theme(axis.text.x=element_text(angle=45, hjust=1, vjust=1)) +
    ylab("Percent of repertoire") +
    xlab("") +
    scale_y_continuous(labels=percent) +
    scale_color_brewer(palette="Set1") +
    geom_point(aes(color=SAMPLE), size=5, alpha=0.8) +
    facet_grid(. ~ ISOTYPE)
plot(g3)</pre>
```

Clonal Usage

Instead of calculating abundance by sequence or clone count, abundance can be calculated using copy numbers for the individual sequences. This is accomplished by passing a copy number column to the copy argument (copy="DUPCOUNT"). Specifying both clone and copy arguments is not meaningful and will result in the clone argument being ignored.

```
# Calculate V family copy numbers by sample and isotype
family <- countGenes(ExampleDb, gene="V_CALL", groups=c("SAMPLE", "ISOTYPE"),
                    mode="family", copy="DUPCOUNT")
head(family, n=4)
## # A tibble: 4 x 7
               SAMPLE, ISOTYPE [3]
## # Groups:
##
     SAMPLE ISOTYPE GENE SEQ_COUNT COPY_COUNT
                                                 SEQ_FREQ_COPY_FREQ
##
      <chr>
              <chr> <chr>
                               <int>
                                          <int>
                                                     <dbl>
                                                               <dbl>
## 1
        +7d
                IgG IGHV3
                                 516
                                           1587 0.9772727 0.9838810
## 2
        +7d
                IgA IGHV3
                                 240
                                           1224 0.9022556 0.9350649
## 3
        -1h
                IgM IGHV3
                                 237
                                            250 0.4209591 0.3858025
```

The output data.frame includes the SEQ_COUNT and SEQ_FREQ columns as previously defined, as well as the additional copy number columns COPY_COUNT and COPY_FREQ reflected the summed copy number (DUPCOUNT) for each sequence within the given GENE, SAMPLE and ISOTYPE.

```
# Subset to IgM and IgG for plotting
family <- filter(family, ISOTYPE %in% c("IgM", "IgG"))
# Plot V family copy abundance by sample and isotype
g4 <- ggplot(family, aes(x=GENE, y=COPY_FREQ)) +
    theme_bw() +
    ggtitle("Copy Number") +
    theme(axis.text.x=element_text(angle=45, hjust=1, vjust=1)) +
    ylab("Percent of repertoire") +
    xlab("") +
    scale_y_continuous(labels=percent) +
    scale_color_brewer(palette="Set1") +
    geom_point(aes(color=SAMPLE), size=5, alpha=0.8) +
    facet_grid(. ~ ISOTYPE)
plot(g4)</pre>
```
