Contents

Example data	1
Generate a clonal abundance curve	2
Generate a diversity curve	3
View diversity tests at a fixed diversity order	5

The clonal diversity of the repertoire can be analyzed using the general form of the diversity index, as proposed by Hill in:

Hill, M. Diversity and evenness: a unifying notation and its consequences. Ecology 54, 427-432 (1973).

Coupled with resampling strategies to correct for variations in sequencing depth, as well as inference of complete clonal abundance distributions as described in:

Chao A, et al. Rarefaction and extrapolation with Hill numbers:

A framework for sampling and estimation in species diversity studies.

Ecol Monogr. 2014 84:45-67.

Chao A, et al. Unveiling the species-rank abundance distribution by generalizing the Good-Turing sample coverage theory. Ecology. 2015 96, 11891201.

This package provides methods for the inference of a complete clonal abundance distribution (using the estimateAbundance function) along with two approaches to assess the diversity of these distributions:

- 1. Generation of a smooth diversity (D) curve over a range of diversity orders (q) using alphaDiversity, and
- 2. A significance test of the diversity (D) at a fixed diversity order (q).

Example data

A small example AIRR database, ExampleDb, is included in the alakazam package. Diversity calculation requires the clone field (column) to be present in the AIRR file, as well as an additional grouping column. In this example we will use the grouping columns sample_id and c_call.

Load required packages
library(alakazam)

```
# Load example data
data(ExampleDb)
```

For details about the AIRR format, visit the AIRR Community documentation site.

Generate a clonal abundance curve

A simple table of the observed clonal abundance counts and frequencies may be generated using the countClones function either with or without copy numbers, where the size of each clone is determined by the number of sequence members:

```
# Partitions the data based on the sample column
clones <- countClones(ExampleDb, group="sample_id")</pre>
head(clones, 5)
## # A tibble: 5 x 4
## # Groups:
                sample_id [1]
     sample_id clone_id seq_count seq_freq
                   <dbl>
##
     <chr>
                              <int>
                                        <dbl>
## 1 +7d
                    3128
                                100
                                       0.100
## 2 +7d
                    3100
                                 50
                                      0.0501
## 3 +7d
                    3141
                                 44
                                      0.0440
## 4 +7d
                    3177
                                 30
                                       0.0300
## 5 +7d
                    3170
                                 28
                                       0.0280
```

You may also specify a column containing the abundance count of each sequence (usually copy numbers), that will including weighting of each clone size by the corresponding abundance count. Furthermore, multiple grouping columns may be specified such that <code>seq_freq</code> (unwieghted clone size as a fraction of total sequences in the group) and <code>copy_freq</code> (weighted faction) are normalized to within multiple group data partitions.

```
# Partitions the data based on both the sample id and c call columns
# Weights the clone sizes by the duplicate_count column
clones <- countClones(ExampleDb, group=c("sample_id", "c_call"), copy="duplicate_count", clones</pre>
head(clones, 5)
## # A tibble: 5 x 7
## # Groups:
               sample_id, c_call [2]
     sample_id c_call clone_id seq_count copy_count seq_freq copy_freq
##
                          <dbl>
##
     <chr>
                <chr>
                                     <int>
                                                 <dbl>
                                                          <dbl>
                                                                     <dbl>

While countClones will report observed abundances, it will not provide confidence intervals. A complete clonal abundance distribution may be inferred using the estimateAbundance function with confidence intervals derived via bootstrapping.

29

This output may be visualized using the plotAbundanceCurve function.

The function alphaDiversity performs uniform resampling of the input sequences and recalculates the clone size distribution, and diversity, with each resampling realization. Diversity (D) is calculated over a range of diversity orders (q) to generate a smooth curve.

Significance testing across groups is performed using the delta of the bootstrap distributions between groups when running alphaDiversity for all values of q specified.

```
# Test diversity at q=0, q=1 and q=2 (equivalent to species richness, Shannon entropy,
# Simpson's index) across values in the sample_id column
# 200 bootstrap realizations are performed (nboot=200)
isotype_test <- alphaDiversity(ExampleDb, group="c_call", min_q=0, max_q=2, step_q=1, nboot=20
# Print P-value table
print(isotype_test@tests)
## # A tibble: 18 x 5
